Manitoba Soil Resource Section,  
Soils and Crops Branch, Manitoba Agriculture.

Printed February, 1999

## PREFACE

This is one of a new series of information bulletins for individual rural municipalities of Manitoba. They serve to introduce the newly developed digital soil databases and illustrate several typical derived and interpretive map products for agricultural land use planning applications. The bulletins will also be available in diskette format for each rural municipality.

Information contained in this bulletin may be quoted and utilized with appropriate reference to the originating agencies. The authors and originating agencies assume no responsibility for the misuse, alteration, re-packaging, or re-interpretation of the information.

This information bulletin serves as an introduction to the land resource information available for the municipality. More detailed information, including copies of the primary soil and terrain maps at larger scales, may be obtained by contacting

Land Resource Unit  
Room 360 Ellis Bldg, University of Manitoba  
Winnipeg, Manitoba R3T 2N2  
Phone: 204-474-6118 FAX: 204-474-7633

## CITATION

Land Resource Unit, 1999. Soils and Terrain. An Introduction to the Land Resource. Rural Municipality of Hanover. Information Bulletin 98-23, Brandon Research Centre, Research Branch, Agriculture and Agri-Food Canada

## ACKNOWLEDGMENTS

Continuing support for this project has been provided by Brandon Research Centre and PFRA Manitoba. The project was initiated by the Land Resource Unit under the Canada-Manitoba Agreement of Agricultural Sustainability.

The following individuals and agencies contributed significantly to the compilation, interpretation, and derivation of the information contained in this report.

Managerial and administrative support was provided by:

R.G. Eilers, Head, Land Resource Unit, Brandon Research Centre, Research Branch, Agriculture and Agri-Food Canada.  
G.J. Racz, Head, Department of Soil Science, University of Manitoba.

Technical support was provided by:

G.W. Lelyk, and P. Cyr, Land Resource Unit, Brandon Research Centre, Research Branch, Agriculture and Agri-Food Canada.  
J. Fitzmaurice, and A. Waddell, Department of Soil Science, University of Manitoba.  
G.F. Mills, P. Ag, Winnipeg, Manitoba  
J. Griffiths, and C. Aglugub, Soil Resource Section, Soils and Crops Branch, Manitoba Agriculture.  
R. Lewis, PFRA, Agriculture and Agri-Food Canada.

Professional expertise for data conversion, correlation, and interpretation was provided by:

W.R. Fraser and R.G. Eilers, Land Resource Unit, Brandon Research Centre, Research Branch, Agriculture and Agri-Food Canada.  
P. Haluschak and G. Podolsky, Soil Resource Section, Soils and Crops Branch, Manitoba Agriculture.

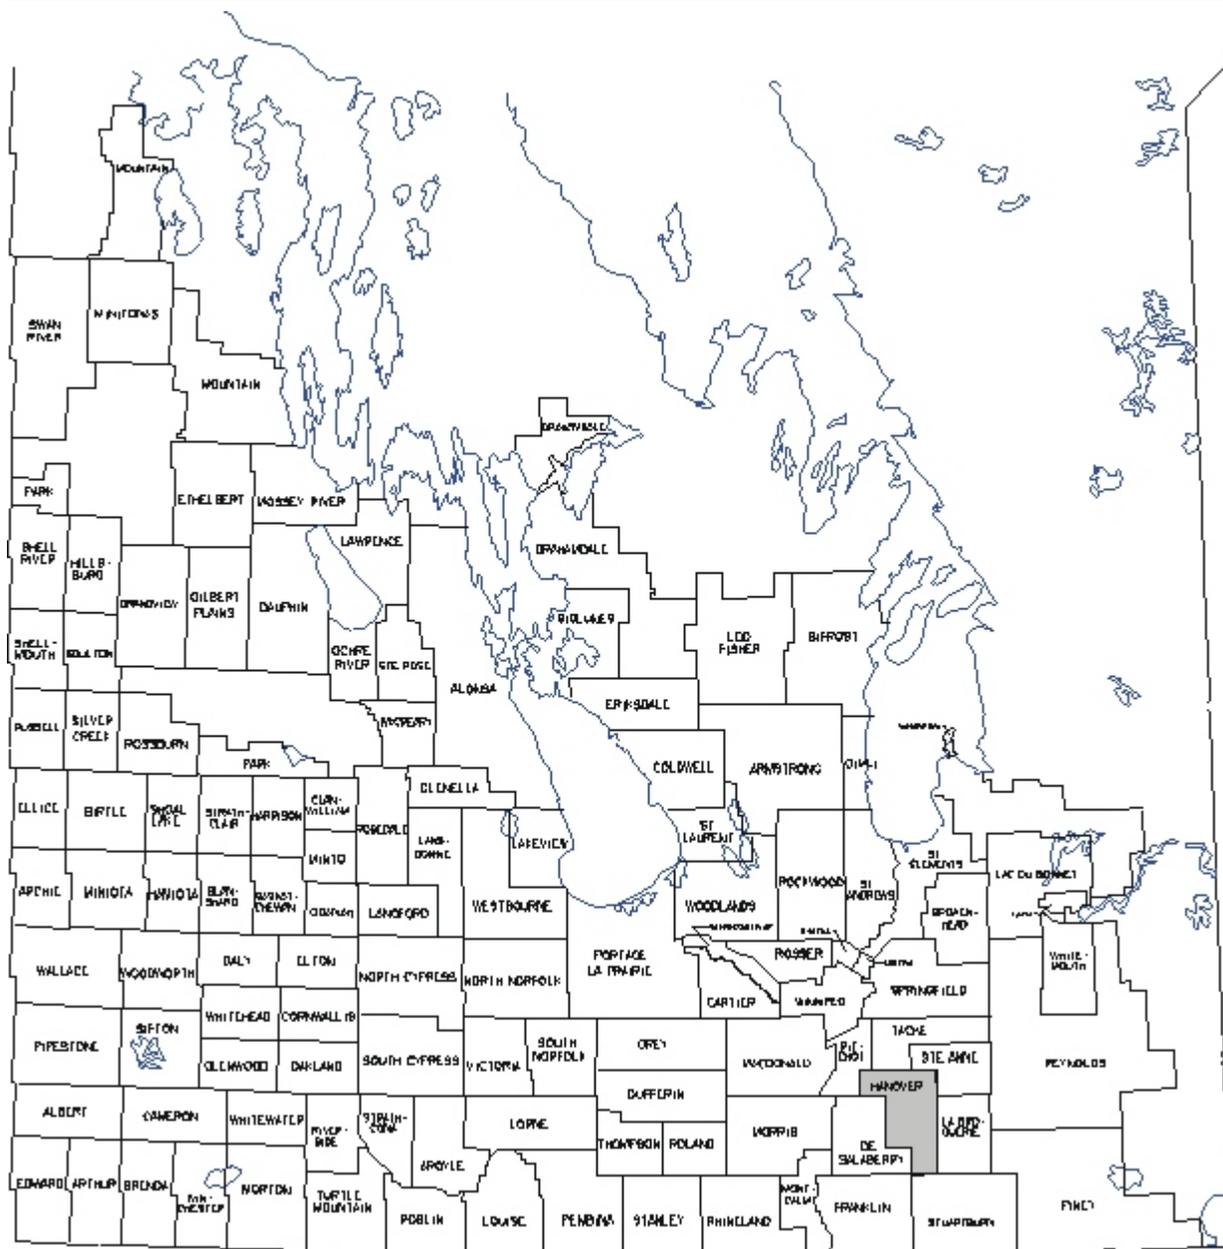

Figure 1. Rural municipalities of southern Manitoba.

## INTRODUCTION

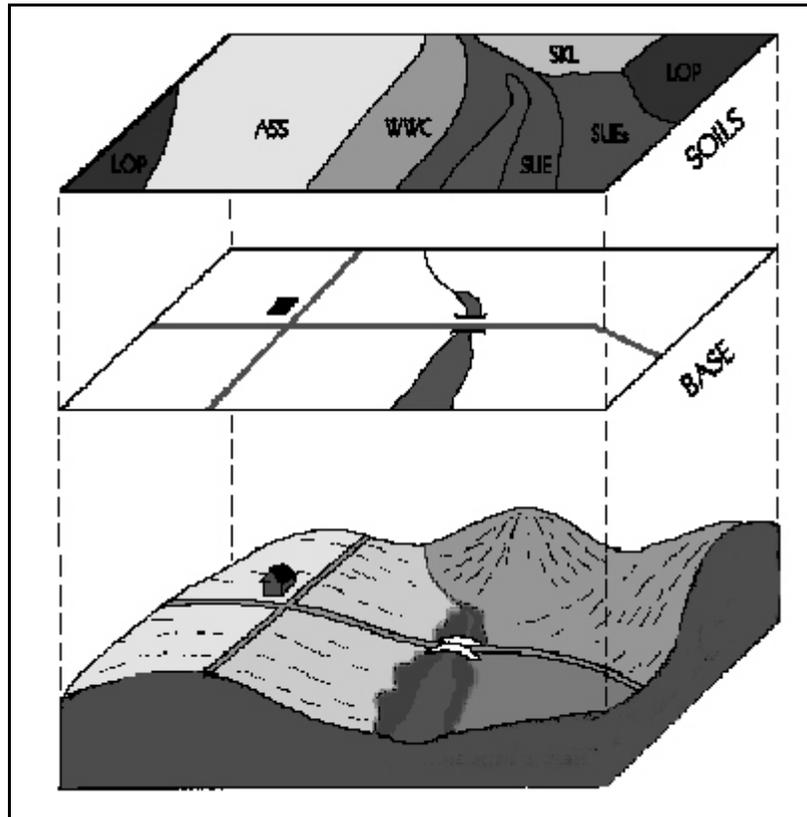

The location of the Rural Municipality of Hanover is shown in Figure 1. A brief overview of the database information, and general environmental conditions for the municipality are presented. A set of maps derived from the data for typical agricultural land use and planning applications are also included.

The soil map and database were compiled and registered using the Geographic Information System (PAMAP GIS) facilities of the Land Resource Unit. These databases were used in the GIS to create the generalized, derived and interpretive maps and statistics in this report. The final maps were compiled and printed using Coreldraw.

This bulletin is available in printed or digital format. The digital bulletin is a Windows based executable file which offers additional display options, including the capability to print any portion of the bulletin.

## LAND RESOURCE DATA

The soil and terrain information presented in this bulletin was compiled as part of a larger project to provide a uniform level of land resource information for agricultural and regional planning purposes throughout Agro-Manitoba. This information was compiled and analysed in two distinct layers as shown in Figure 2.

**Figure 2.** Soil and Base Map data.

## Base Layer

Digital base map information includes the municipality and township boundaries, along with major streams, roads and highways. Major rivers and lakes from the base layer were also used as common boundaries for the soil map layer. Water bodies larger than 25 ha in size were digitized as separate polygons.

## Soil Layer

The most detailed soil information currently available was selected as the data source for the digital soil layer for each rural municipality.

Comprehensive detailed soil maps (1:20 000 to 1:50 000 scale) have been published for many rural municipalities. Where they were available, the individual soil map sheets were digitized and compiled as a single georeferenced layer to match the digital RM base. Map polygons have one or more soil series components, as well as slope and stoniness classes. Soil database information was produced for each polygon, to meet national standards (MacDonald and Valentine, 1992). Slope length classes were also added, based on photo-interpretation.

Older, reconnaissance scale soil maps (1:126 720 scale) represented the only available soil data source for many rural municipalities. These maps were compiled on a **soil association** basis, in which soil landscape patterns were identified with unique surficial geological deposits and textures. Each soil association consists of a range of different soils ("associates") each of which occurs in a repetitive position in the landscape. Modern soil series that best represent the soil association were identified for each soil polygon. The soil and modifier codes provide a link to additional databases of soil properties. In this way, both detailed and reconnaissance soil map polygons were related to soil drainage, surface texture, and other soil properties to produce various interpretive maps. Slope length classes were also added, based on photo-interpretation.

## SOIL AND TERRAIN OVERVIEW

The Rural Municipality (RM) of Hanover covers an area of 8 townships (approximately 77 200 ha) in southeastern Manitoba. It is located some 20 km southeast of the City of Winnipeg (page 3). The town of Steinbach is the largest population and service centre although agricultural and other services are also provided from smaller towns and villages (Blumenort, Grunthal, Kleefeld, Mitchell, New Bothwell, Niverville and Randolph).

The climate in the area can be related to weather data from Steinbach located in the northeast portion of the municipality. The mean annual temperature is 2.4°C and the mean annual precipitation is 510 mm (Environment Canada, 1993). The average frost-free period is 115 days and degree-days above 5°C accumulated from May to September average 1644 (Ash, 1991). An evaluation of growing conditions in this region of Manitoba can be related to estimates of seasonal moisture deficit and effective growing degree-days (EGDD) above 5°C. The seasonal moisture deficit calculated between May and September is slightly less than 250 mm and the estimated effective growing degree-days accumulated from May to September average between 1500 and 1600 (Agronomic Interpretations Working Group, 1995). These parameters provide an indication of moisture and heat energy available for crop growth and are generally adequate to support a wide range of crops adapted to western Canada.

Physiographically, the RM of Hanover is located entirely in the Manitoba Plain and consists of two distinct landscapes divided between the level to very gently sloping Red River Valley in the northern part of the area and the gently sloping, slightly ridged terrain of the Southeastern Plain in the south (Canada-Manitoba Soil Survey, 1980). Elevation of the land surface varies from about 290 metres above sea level (m asl) in the southeast corner of the municipality, decreasing to about 232 m asl in the northwest corner. Local relief is generally under 3 metres and slopes are less than 2 percent (page 9). The low surface gradient of 1.6 m/km or 8.5 ft/mi in the Southeastern Plain decreases to about 0.4 m/km or 1.5 ft/mile in

the Red River Valley resulting in poorly developed surface drainage throughout the municipality. Surface waters drain very slowly in a northwesterly direction via Joubert and Tourond Creeks and their tributaries. Surface drainage for agricultural purposes is facilitated by a network of man-made drains constructed to enhance runoff and reduce the duration of surface ponding.

Soil materials in the Red River Valley were deposited during the time of glacial Lake Agassiz and consist primarily of clayey lacustrine sediments underlain in local areas by lacustrine silts. Surface texture is dominantly clayey. In contrast, the Southeastern Plain is characterized by thin, sandy to coarse-loamy lacustrine veneers overlying stony, loam textured glacial till. Areas of waterworked, extremely calcareous, stony, loam till and local areas of gravelly sand outwash and beach deposits are also common (page 11). The flat topography throughout the area and the high clay content of the Red River Valley result in the majority of soils being classified as imperfectly to poorly drained (page 13).

Soils in the municipality have been mapped at a semi-detailed 1:50000 scale, described in detail, and published in the report, Soils of the Rural Municipality of Hanover (Hopkins et al., 1993). Detailed 1:20000 scale soil information is available for small areas around the towns of Blumenort, Grunthal, Kleefeld, Mitchell, New Bothwell and Niverville (Hopkins et al., 1993). According to the Canadian System of Soil Classification (Soil Classification Working Group, 1998), Black Chernozem soils in association with Humic Gleysols are dominant in the northern portion and Chernozemic Dark Gray soils associated with Humic Gleysols and local occurrence of Organic soils are dominant in the south. The majority of soils are non-saline although an area of weak salinity occurs in the vicinity of New Bothwell, usually in association with imperfectly and poorly drained clayey soils (page 15). Other management considerations are primarily related to texture (sandy and clayey soils) and wetness (page 17). Seasonal high water tables (at 1 to 2 metres) and saturated soils are common. Moderately to excessively stony conditions occur in the till soils in the southern part of the municipality.

Most of the soils in the municipality are rated in **Class 2** (34 percent) and **Class 3** (37 percent) for agricultural capability with moderate to moderately severe limitations for agriculture (page 19). **Class 4** soils (nearly 5 percent) are considered marginally arable. About 50 percent of the soils are rated as **Good to Fair** for irrigation suitability whereas the remainder are rated as **Poor**, primarily due to fine texture and poor drainage (page 21). The major problem limiting the agricultural use of soils is inadequate drainage. Unfavourable workability, stoniness, droughtiness and potential degradation due to erosion by wind are other important limitations.

One of the issues currently receiving considerable attention is the sustainability of agricultural practices and their potential impact on the soil and groundwater environment. To assist in highlighting this concern to land planners and agricultural producers, an assessment of potential environmental impact (EI) under irrigation has been included in this bulletin (page 23). As shown, the majority of the municipality is at **Minimal to Low** risk of degradation due mainly to the heavy texture of the soil and the slow drainage. These conditions reduce the risk of deep leaching of potential contaminants on the soil surface. In contrast, the risk for leaching is **High** on poorly and imperfectly drained sandy soils in which the water table is close to the surface. This EI map is intended to be used in association with the irrigation suitability map.

Another issue of concern to producers, soil conservationists and land use specialists is soil erosion caused by agricultural cropping and tillage practices. Areas with potential for water erosion and where special practices should be adopted to mitigate this risk are shown on page 25. Almost 80 percent of the land in the municipality is at a **Low to Negligible** risk of degradation due to water erosion. The very flat topography and the soil texture (sandy and clayey textures) are the main reasons for the low risk. Management practices focus primarily on maintaining adequate crop residues to provide sufficient surface cover.

Land use in the RM of Hanover is primarily agricultural with small areas of woodland, pasture, urban development and recreation land. An assessment of the status of land use in 1994 was obtained through an analysis of satellite imagery. It showed that annual crops occupied about 45 percent of the land in the RM with forage production taking place on 12 percent of the municipality and grassland occupying 22 percent. The remaining areas are in trees (15 percent) and wetlands (0.7 percent). Various non-agricultural uses such as infrastructure for urban areas, transportation and recreation occupy about 5 percent of the municipality (page 27).

While the majority of soils in the RM of Hanover have moderate to moderately severe limitations for arable agriculture, the clayey textured soils require management practices which maintain adequate surface drainage, soil structure and tillage. The coarse-textured sandy soils require careful management to protect against the risk of wind erosion. This includes leaving adequate crop residues on the surface to provide sufficient trash cover during the early spring period. The provision of shelter belts, minimum tillage practices, and crop rotations including forages will help to reduce the risk of soil degradation and maintain productivity.

A major portion of the municipality has low relief and a dominance of imperfectly to poorly drained soils. Clayey soils with slow to very slow permeability are subject to surface ponding and slow runoff unless adequate drainage is provided. This situation arises most often during spring snowmelt or following heavy rains. In contrast, the sandy soils are much more permeable near the surface but because of the presence of a loamy till subsoil, they typically have seasonal high water tables. Consequently, improvement and maintenance of water management infrastructure on a regional basis is required to reduce surface ponding while maintaining adequate soil moisture for crop growth.

## DERIVED AND INTERPRETIVE MAPS

A large variety of computer derived and interpretive maps can be generated from the digital soil and landscape databases. These maps are based on selected combinations of database values and assumptions.

**Derived maps** show information that is given in one or more columns in the computer map legend (such as soil drainage, soil salinity, or slope class).

**Interpretive maps** portray more complex land evaluations based on a combination of soil and landscape information. Interpretations are based on soil and landscape conditions in each polygon. Interpretative maps typically show land capabilities, suitabilities, or risks related to sustainability.

Several examples of derived and interpretive maps are included in this information bulletin:

### Derived Maps

Slope

Surface Texture

Drainage

Salinity

Management Considerations

### Interpretative Maps

Agricultural Capability

Irrigation Suitability

Potential Environmental Impact

Water Erosion Risk

Land Use

The maps have all been reduced in size and generalized (simplified) in order to portray conditions for an entire rural municipality on one page. These generalized maps provide a useful overview of conditions within a municipality, but are not intended to apply to site specific land parcels. On-site evaluations are recommended for localized site specific land use suitability requirements.

Digital databases derived from recent detailed soil inventories contain additional detailed information about significant inclusions of differing soil and slope conditions in each map polygon. This information can be portrayed at larger map scale than shown in this bulletin.

Information concerning particular interpretive maps, and the primary soil and terrain map data, can be obtained by contacting the Manitoba Soil Resource Section of Manitoba Agriculture, the local PFRA office, or the Manitoba Land Resource Unit.

**Slope Map.**

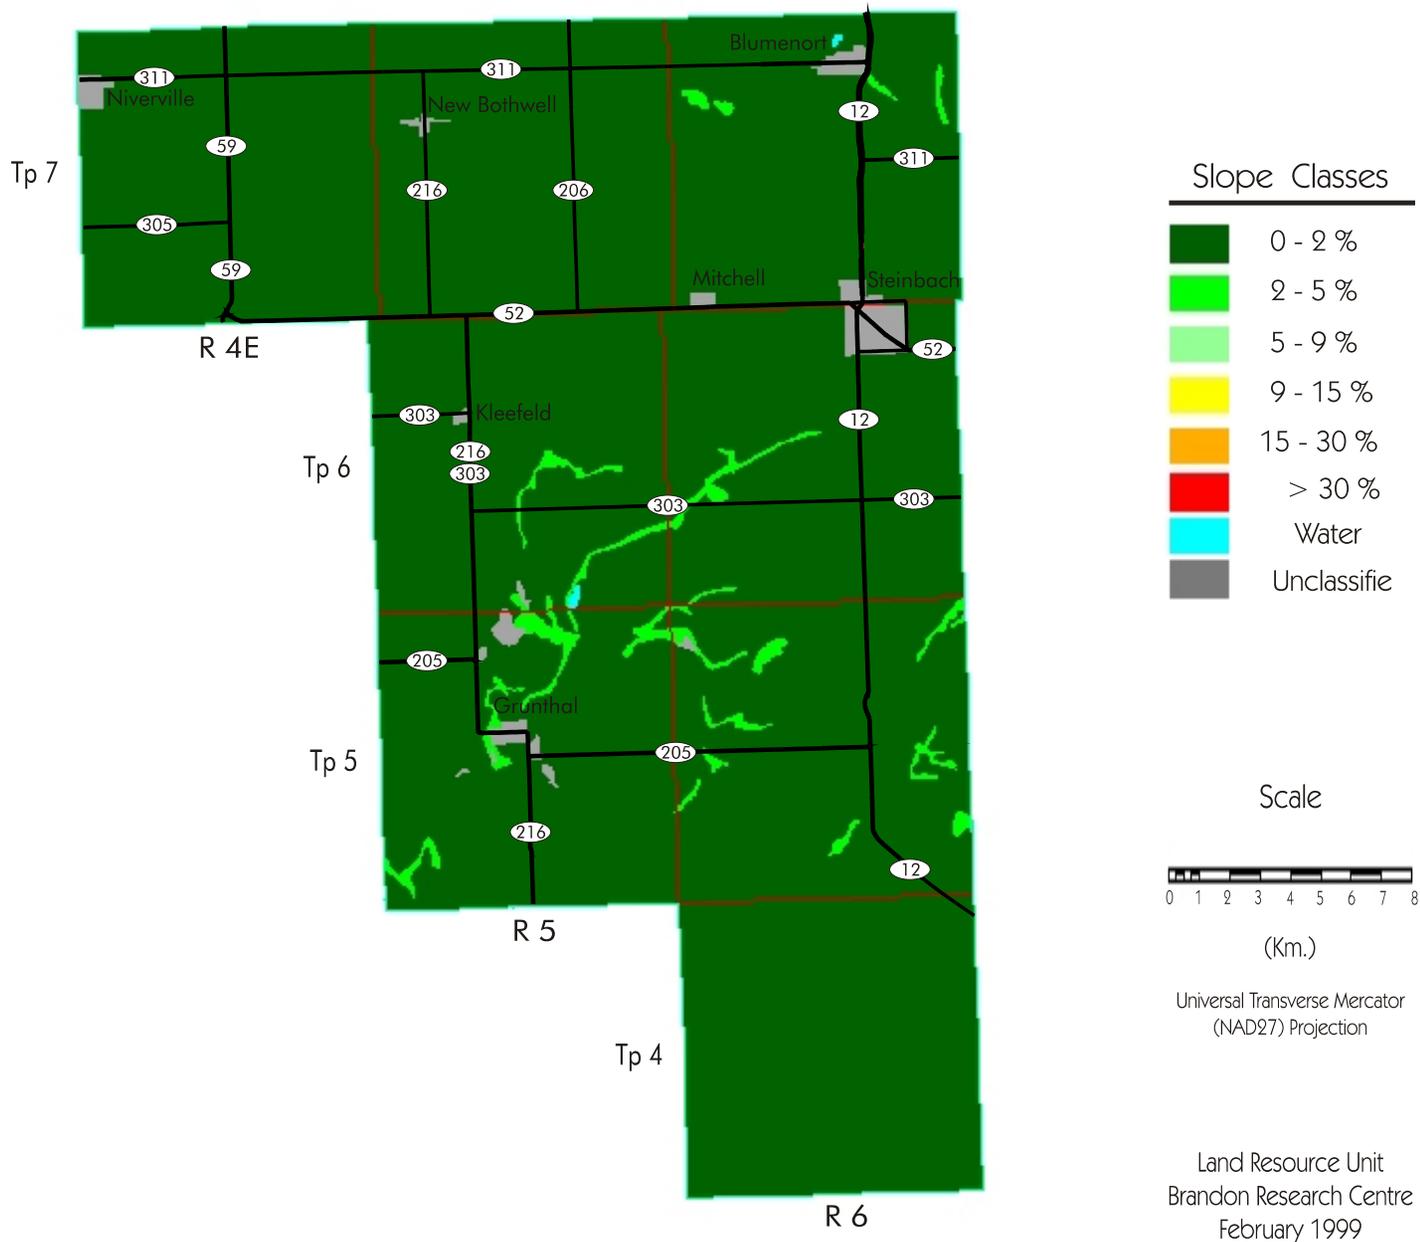

Slope describes the steepness of the landscape surface. The slope classes shown on this map are derived from the digital soil and terrain layer database. Specific colours are used to indicate the dominant slope class for each polygon in the RM. Additional slope classes may occur in each polygon area, but cannot be portrayed at this reduced map scale.

**Table 1. Slope Classes<sup>1</sup>**

<b>Slope Class</b>	<b>Area (ha)</b>	<b>Percent of RM</b>
<b>0 - 2 %</b>	<b>74726</b>	<b>96.9</b>
<b>2 - 5 %</b>	<b>1357</b>	<b>1.8</b>
<b>5 - 9 %</b>	<b>0</b>	<b>0.0</b>
<b>9 - 15 %</b>	<b>0</b>	<b>0.0</b>
<b>15 - 30 %</b>	<b>0</b>	<b>0.0</b>
<b>&gt; 30 %</b>	<b>0</b>	<b>0.0</b>
<b>Unclassified</b>	<b>1042</b>	<b>1.4</b>
<b>Water</b>	<b>17</b>	<b>0.0</b>
<b>Total</b>	<b>77143</b>	<b>100.0</b>

<sup>1</sup> Area has been assigned to the dominant slope in each soil polygon.

# Slope Map

**Surface Texture Map.**

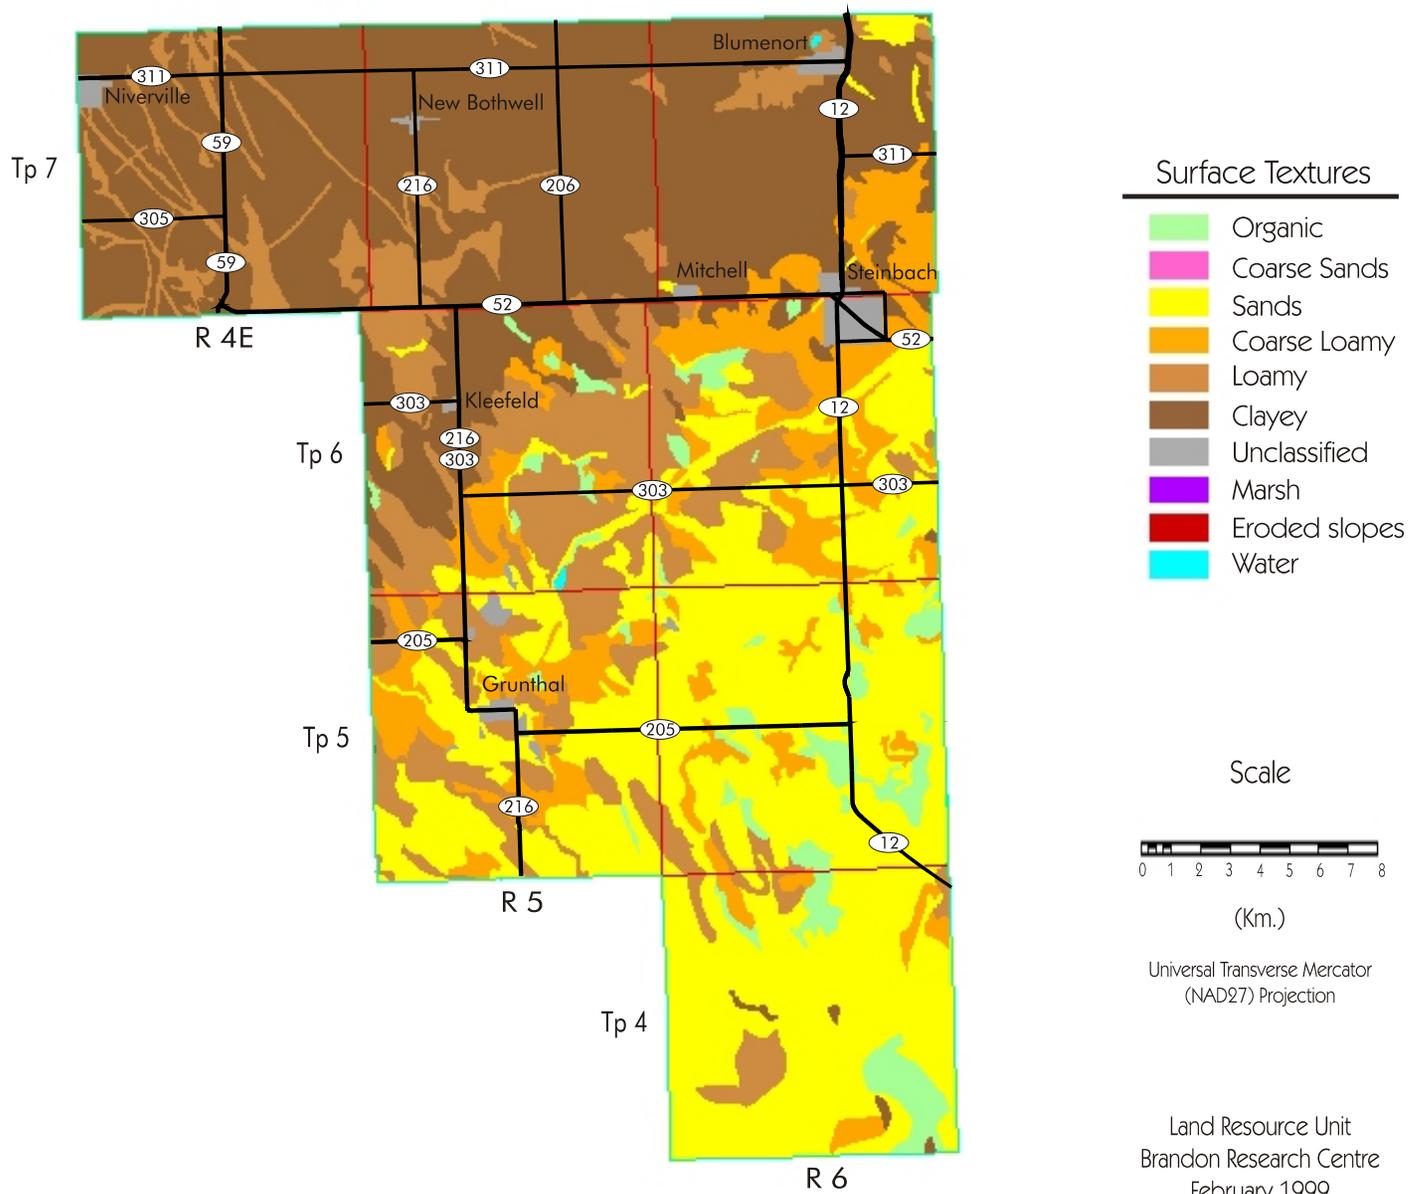

The soil textural class for the upper most soil horizon of the dominant soil series within a soil polygon was utilized for classification. Texture may vary from that shown with soil depth and location within the polygon.

**Table 2. Surface Texture<sup>1</sup>**

<b>Surface Texture</b>	<b>Area (ha)</b>	<b>Percent of RM</b>
<b>Organics</b>	<b>2560</b>	<b>3.3</b>
<b>Coarse Sands</b>	<b>0</b>	<b>0.0</b>
<b>Sands</b>	<b>23972</b>	<b>31.1</b>
<b>Coarse Loamy</b>	<b>14163</b>	<b>18.4</b>
<b>Loamy</b>	<b>26785</b>	<b>34.7</b>
<b>Clayey</b>	<b>0</b>	<b>0.0</b>

<b>Total</b>	<b>77143</b>	<b>100.0</b>

<sup>1</sup> Based on the **dominant** soil series for each soil polygon.

# Surface Texture Map

**Soil Drainage Map.**

Drainage is described on the basis of actual moisture content in excess of field capacity, and the length of the saturation period within the plant root zone. Five drainage classes plus three land classes are shown on this map.

**Very Poor** - Water is removed from the soil so slowly that the water table remains at or on the soil surface for the greater part of the time the soil is not frozen. Excess water is present in the soil throughout most of the year.

**Poor** - Water is removed so slowly in relation to supply that the soil remains wet for a large part of the time the soil is not frozen. Excess water is available within the soil for a large part of the time.

**Imperfect** - Water is removed from the soil sufficiently slowly in relation to supply to keep the soil wet for a significant part of the growing season. Excess water moves slowly down the profile if precipitation is the major source.

**Well** - Water is removed from the soil readily but not rapidly. Excess water flows downward readily into underlying materials or laterally as subsurface flow.

**Rapid** - Water is removed from the soil rapidly in relation to supply. Excess water flows downward if underlying material is pervious. Subsurface flow may occur on steep slopes during heavy rainfall.

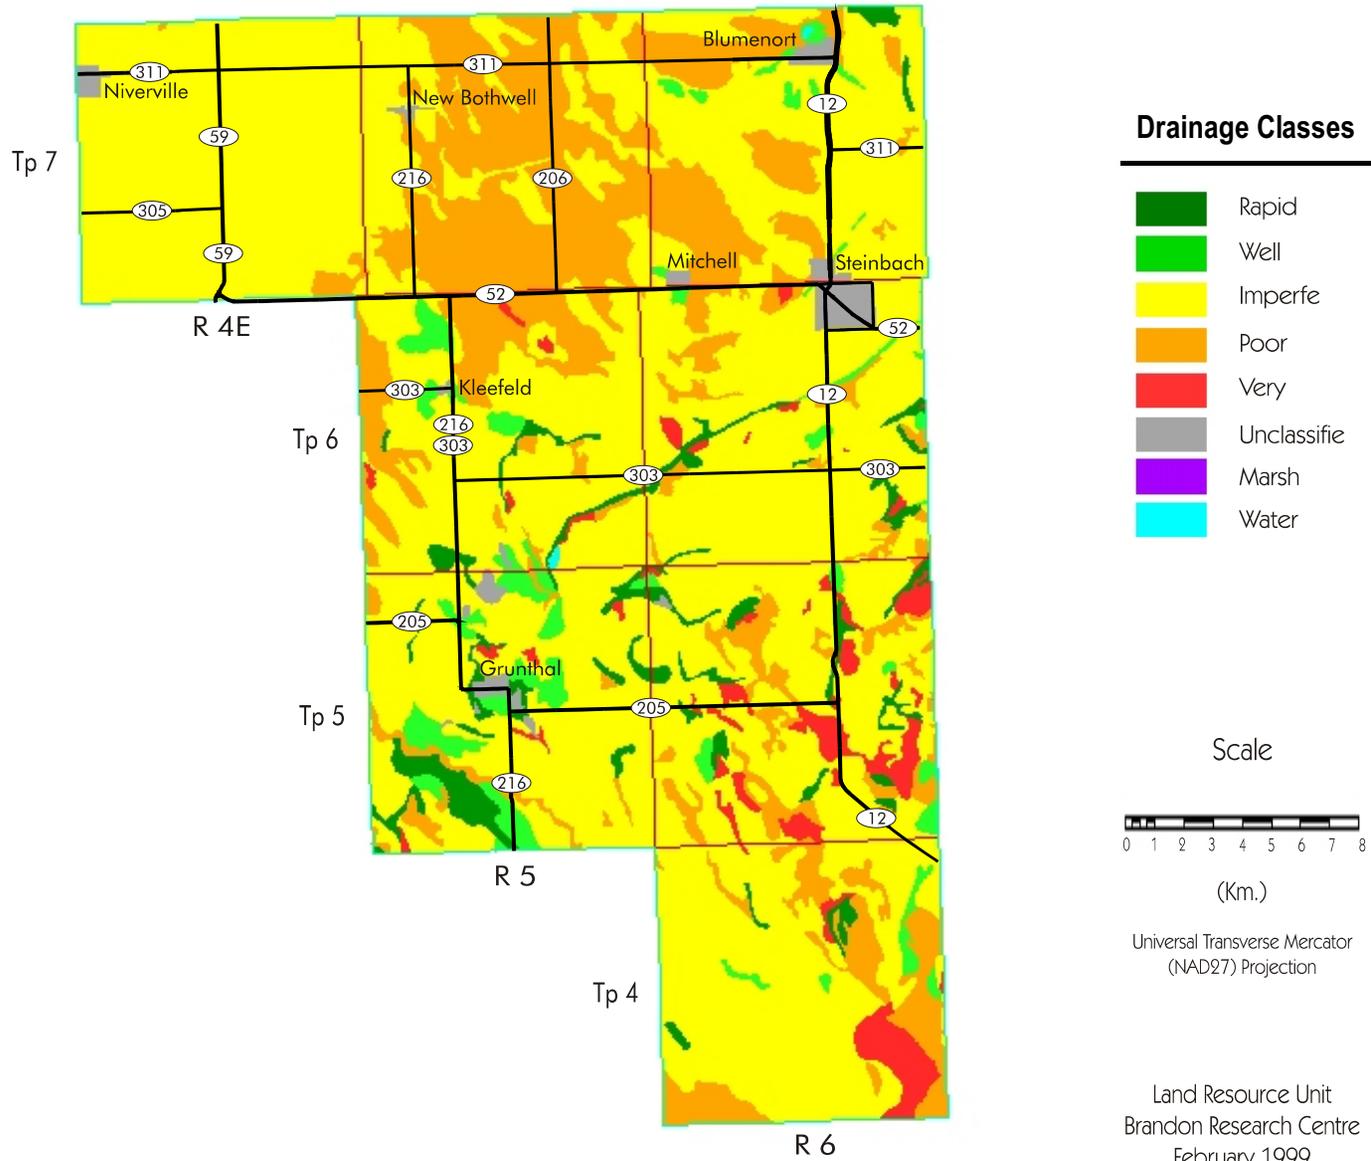

Drainage classification is based on the dominant soil series within each individual soil polygon.

**Table 3. Drainage Classes<sup>1</sup>**

<b>Drainage Class</b>	<b>Area (ha)</b>	<b>Percent of RM</b>
<b>Very Poor</b>	<b>2161</b>	<b>2.8</b>
<b>Poor</b>	<b>15851</b>	<b>20.5</b>
<b>Imperfect</b>	<b>53207</b>	<b>69.0</b>
<b>Well</b>	<b>2416</b>	<b>3.1</b>
<b>Rapid</b>	<b>2449</b>	<b>3.2</b>
<b>Marsh</b>	<b>0</b>	<b>0.0</b>
<b>Unclassified</b>	<b>1042</b>	<b>1.4</b>
<b>Water</b>	<b>17</b>	<b>0.0</b>
<b>Total</b>	<b>77143</b>	<b>100.0</b>

<sup>1</sup> Area has been assigned to the dominant drainage class for each soil polygon.

# Soil Drainage Map

**Soil Salinity Map.**

A saline soil contains soluble salts in such quantities that they interfere with the growth of most crops. Soil salinity is determined by the electrical conductivity of the saturation extract in decisiemens per metre (dS/m). Approximate limits of salinity classes are:

<b>non-saline</b>	< 4 dS/m
<b>weakly saline</b>	4 to 8 dS/m
<b>moderately saline</b>	8 to 15 dS/m
<b>strongly saline</b>	> 15 dS/m

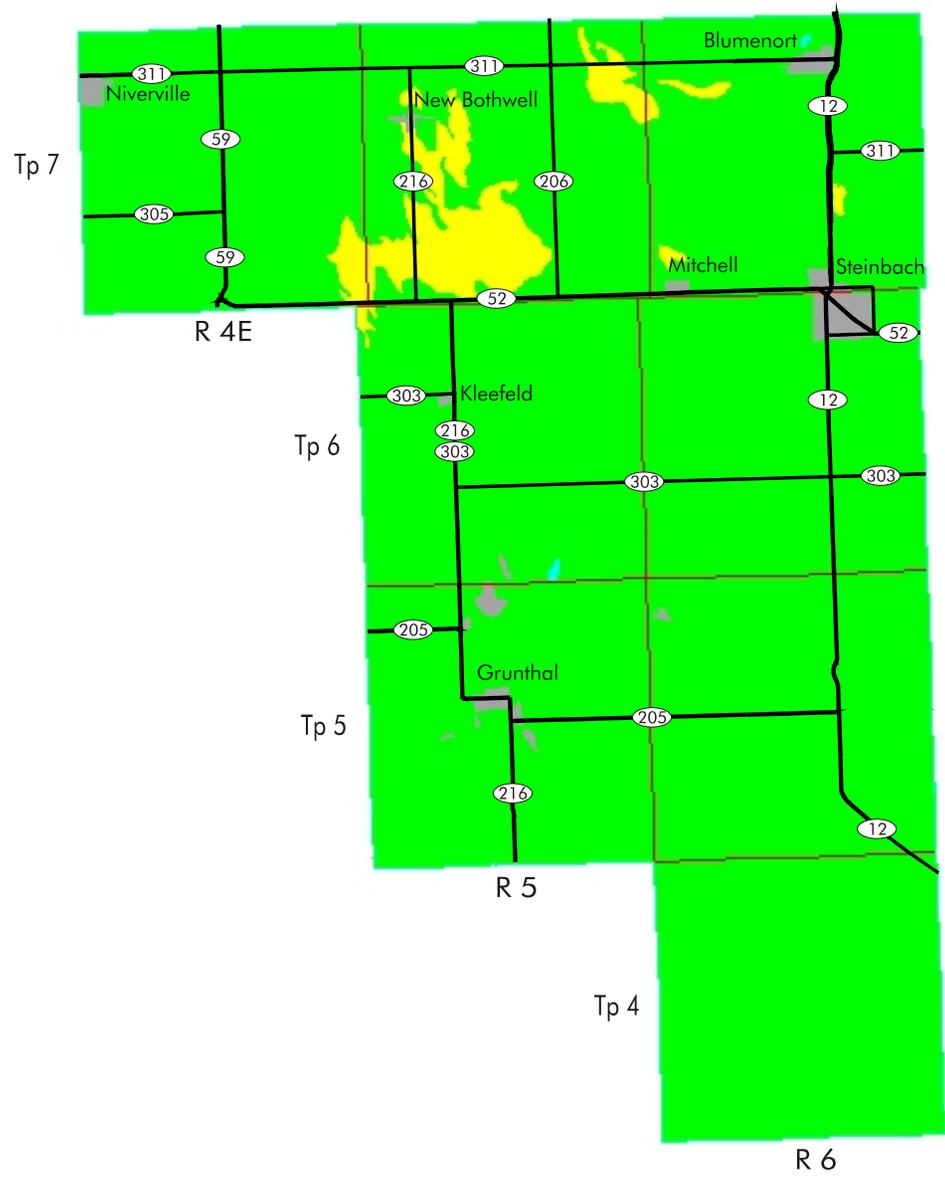

The salinity classification of each individual soil polygon was determined by the most severe salinity classification present within that polygon.

**Table 4. Salinity Classes<sup>1</sup>**

<b>Salinity Class</b>	<b>Area (ha)</b>	<b>Percent of RM</b>
<b>Non Saline</b>	<b>73172</b>	<b>94.9</b>
<b>Weakly Saline</b>	<b>2912</b>	<b>3.8</b>
<b>Moderately Saline</b>	<b>0</b>	<b>0.0</b>
<b>Strongly Saline</b>	<b>0</b>	<b>0.0</b>
<b>Eroded Slopes</b>	<b>0</b>	<b>0.0</b>
<b>Marsh</b>	<b>0</b>	<b>0.0</b>
<b>Unclassified</b>	<b>1042</b>	<b>1.4</b>
<b>Water</b>	<b>17</b>	<b>0.0</b>
<b>Total</b>	<b>77143</b>	<b>100.0</b>

<sup>1</sup> Area has been assigned to the most severe salinity class for each soil polygon.

# Soil Salinity Map

### Salinity Classes

### Management Considerations Map.

Management consideration maps are provided to focus on awareness of land resource characteristics important to land use. This map does not presume a specific land use. Rather it portrays the most common and wide spread attributes that apply to most soil landscapes in the province.

These maps **highlight attributes** of soil-landscapes that the land manager must consider for any intended land use.

- Fine texture
- Medium texture
- Coarse texture
- Topography
- Wetness
- Organic
- Bedrock

**F = Fine texture** - soil landscapes with **fine textured soils (clays and silty clays)**, and thus low infiltration and internal permeability rates. These require special considerations to mitigate surface ponding (water logging), runoff, and trafficability. Timing and type of tillage practices used may be restricted.

**M = Medium texture** - soil landscapes with medium to moderately fine textures (**loams to clay loams**), and good water and nutrient retention properties. Good management and cropping practices are required to minimize leaching and the risk of erosion.

**C = Coarse texture** - soil landscapes with **coarse to very coarse textured soils (loamy sands, sands and gravels)**, have a high permeability throughout the profile, and require special management practices related to application of agricultural chemicals, animal wastes, and municipal effluent to protect and sustain the long term quality of the soil and water resources. The risk of soil erosion can be minimized through the use of shelterbelts and maintenance of crop residues.

**T = Topography** - soil landscapes with **slopes greater than 5%** are steep enough to require special management practices to minimize the risk of erosion.

**W = Wetness** - soil landscapes that have **poorly drained soils and/or >50 % wetlands** (due to seasonal and annual flooding, surface ponding, permanent water bodies (sloughs), and/or high water tables), require special management practices to mitigate adverse impact on water quality, protect subsurface aquifers, and sustain crop production during periods of high risk of water logging.

**O = Organic** - soil landscapes with organic soils, requiring special management considerations of drainage, tillage, and cropping to sustain productivity and minimize subsidence and erosion.

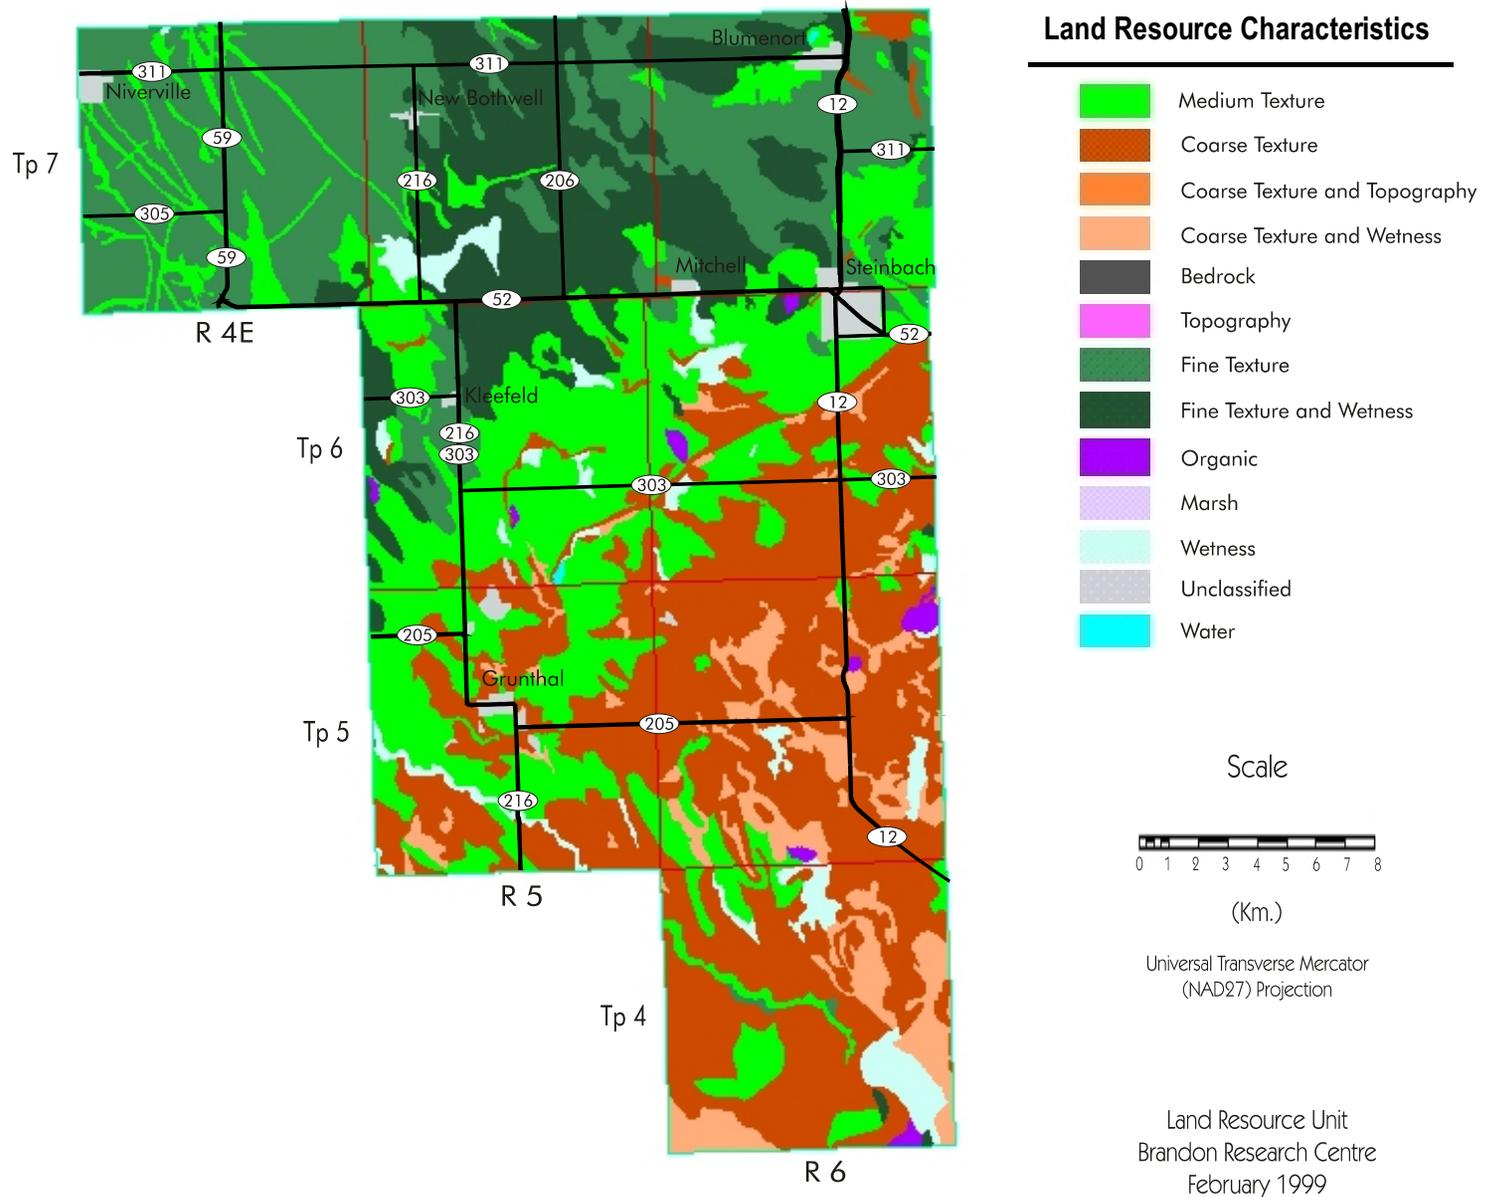

**R = Bedrock** - soil landscapes that have **shallow depth to bedrock (< 50 cm) and/or exposed bedrock** which may prevent the use of some or all tillage practices as well as the range of potential crops. They require special cropping and management practices to sustain agricultural production.

**Table 4. Management Considerations<sup>1</sup>**

Land Resource Characteristics	Area (ha)	Percent of RM
Fine Texture	15990	20.7
Fine Texture and Wetness	10847	14.1
Fine Texture and Topography	0	0.0
Medium Texture	19724	25.6
Coarse Texture	22358	29.0
Coarse Texture and Wetness	4315	5.6
Coarse Texture and Topography	0	0.0
Topography	0	0.0
Bedrock	0	0.0
Wetness	2482	3.2
Organic	367	0.5
Marsh	0	0.0
Unclassified	1042	1.4
Water	17	0.0
<b>Total</b>	<b>77143</b>	<b>100.0</b>

<sup>1</sup> Based on the **dominant** soil series and slope gradient within each polygon.

# Management Considerations Map

**Agricultural Capability Map.**

This evaluation utilizes the 7 class Canada Land Inventory system (CLI, 1965). Classes 1 to 3 represent the prime agricultural land, class 4 land is marginal for sustained cultivation, class 5 land is capable of perennial forages and improvement is feasible, class 6 land is capable of producing native forages and pasture but improvement is not feasible, and class 7 land is considered unsuitable for dryland agriculture. Subclass modifiers include structure and/or permeability (D), erosion (E), inundation (I), moisture limitation (M), salinity (N), stoniness (P), consolidated bedrock (R), topography (T), excess water (W) and cumulative minor adverse characteristics (X).

This generalized interpretive map is based on the dominant soil series and phases for each soil polygon. The CLI subclass limitations cannot be portrayed at this generalized map scale.

**Table 5. Agricultural Capability<sup>1</sup>**

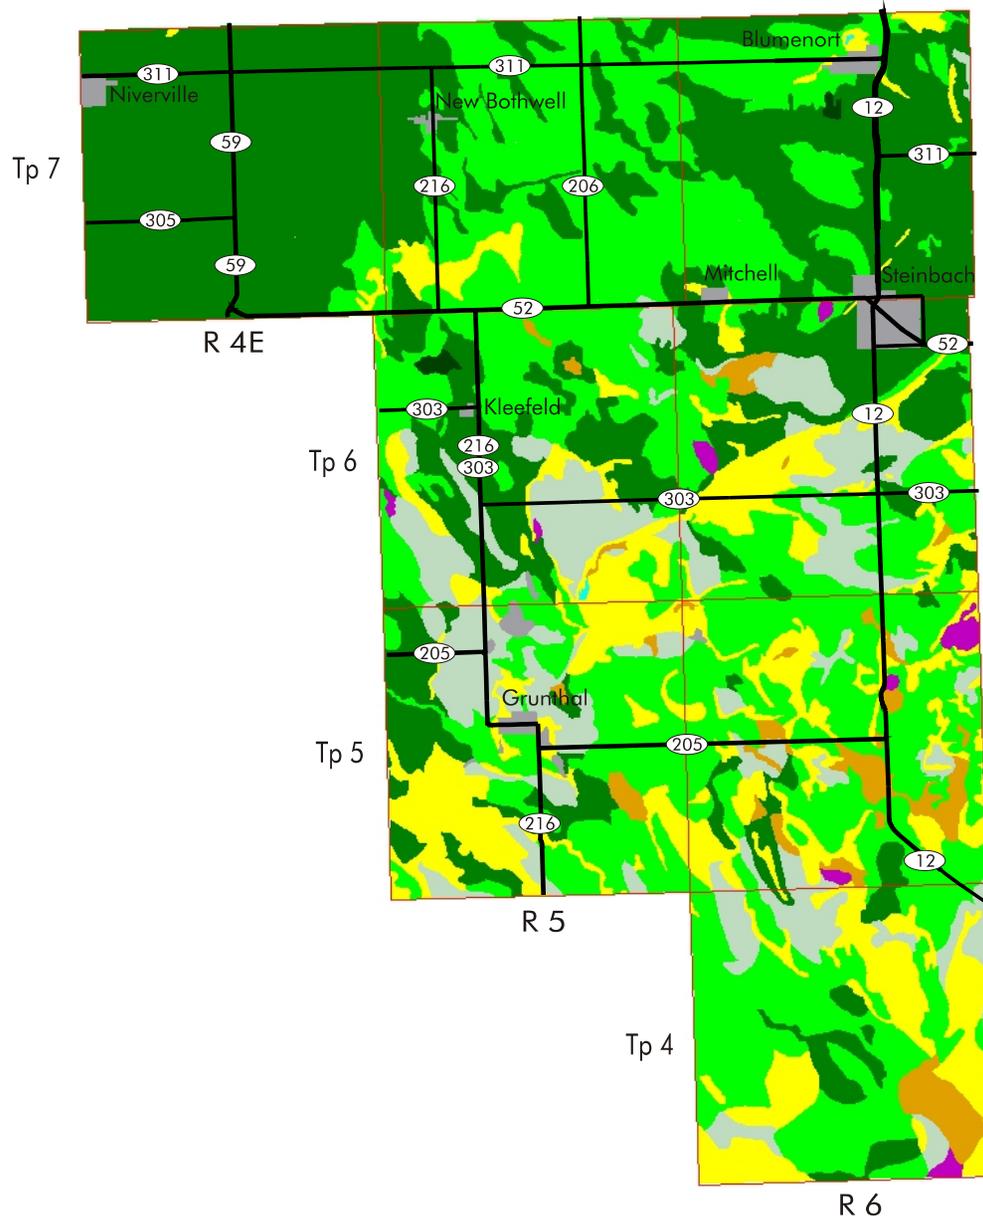

<b>Class Subclass</b>	<b>Area (ha)</b>	<b>Percent of RM</b>

**Irrigation Suitability Map.**

Irrigation ratings are based on an assessment of the most limiting combination of soil and landscape conditions. Soils in the same class have a similar relative suitability or degree of limitation for irrigation use, although the specific limiting factors may differ. These limiting factors are described by subclass symbols at detailed map scales. The irrigation rating system does not consider water availability, method of application, water quality, or economics of irrigated land use.

Irrigation suitability is a four class rating system. Areas with no or slight soil and/or landscape limitations are rated **Excellent** to **Good** and can be considered irrigable. Areas with moderate soil and/or landscape limitations are rated as **Fair** and considered marginal for irrigation providing adequate management exists so that the soil and adjacent areas are not adversely affected by water application. Soil and landscape areas rated as **Poor** have severe limitations for irrigation.

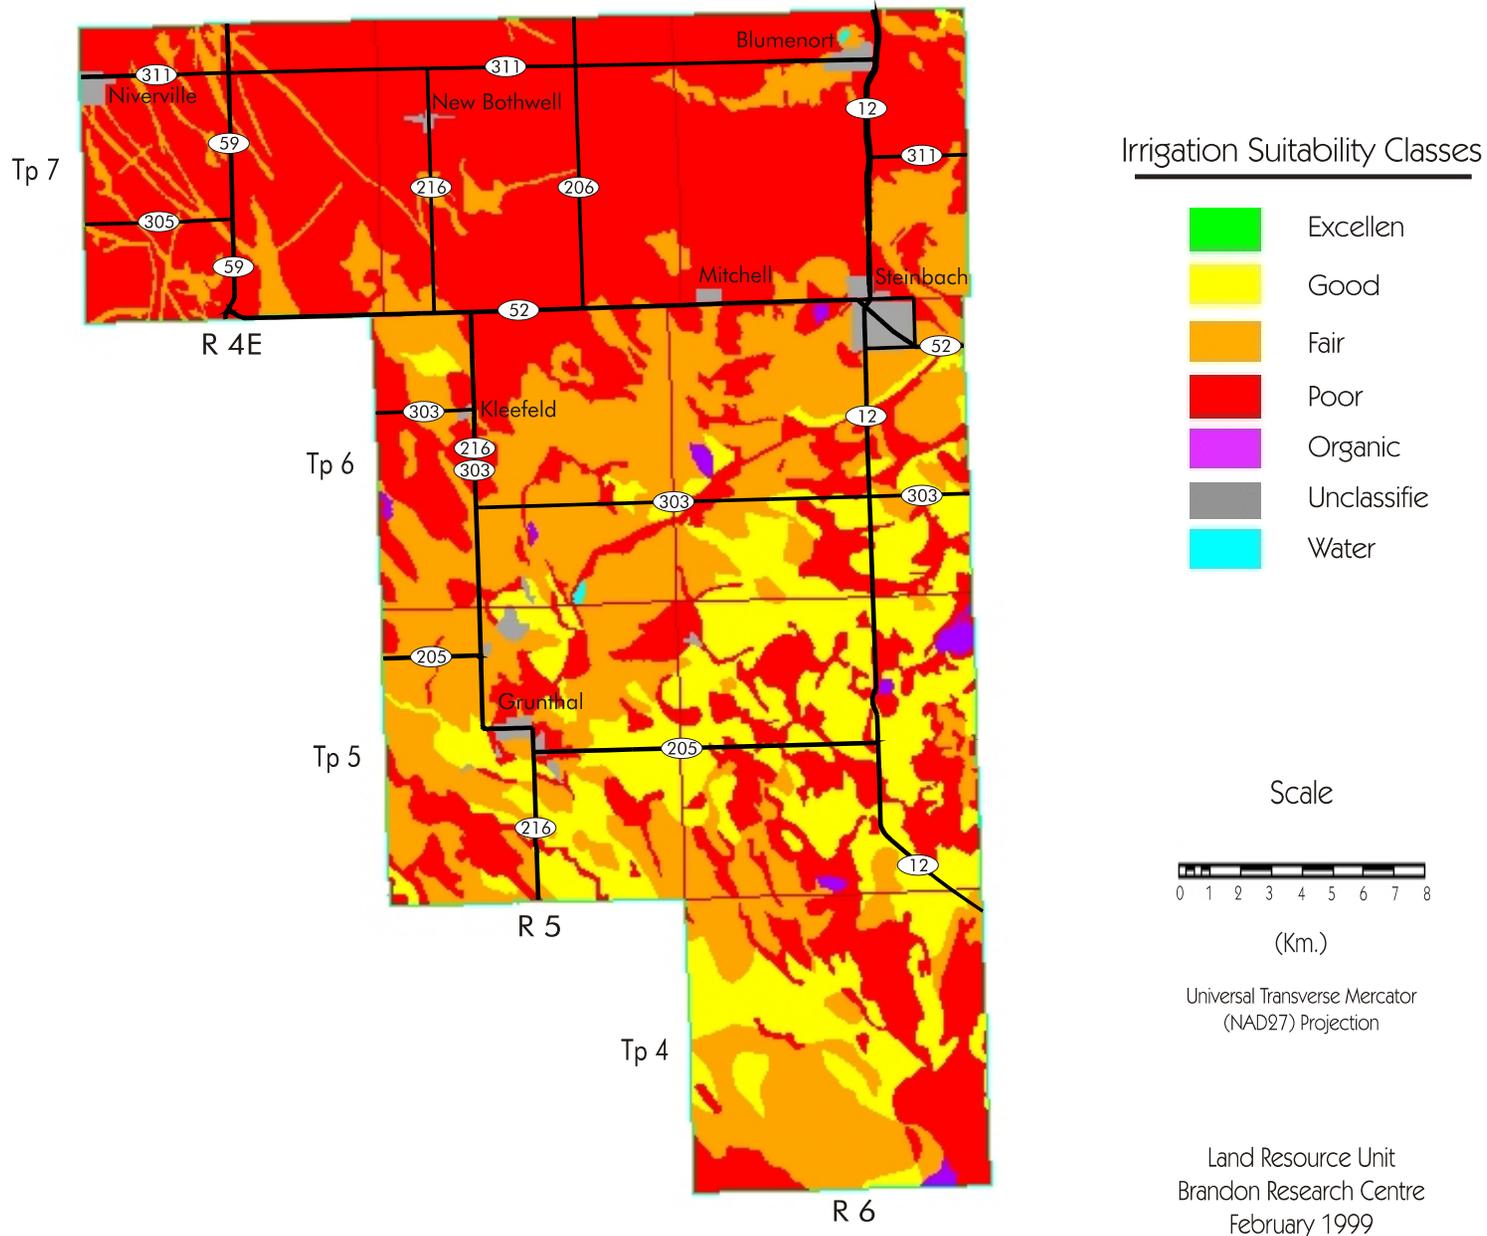

This generalized interpretive map is based on the dominant soil series for each soil polygon, in combination with the dominant slope class. The nature of the subclass limitations and the classification of subdominant components is not shown at this generalized map scale.

**Table 6. Irrigation Suitability<sup>1</sup>**

<b>Class</b>	<b>Area (ha)</b>	<b>Percent of RM</b>
<b>Excellent</b>	<b>0</b>	<b>0.0</b>

# Irrigation Suitability Map

### Potential Environmental Impact Under Irrigation Map.

A major environmental concern for land under irrigated crop production is the possibility that surface and/or ground water may be impacted. The potential environmental impact assessment provides a relative rating of land into 4 classes (minimal, low, moderate and high) based on an evaluation of specific soil factors and landscape conditions that determine the impact potential.

Soil factors considered are those properties that determine water retention and movement through the soil; topographic features are those that affect runoff and redistribution of moisture in the landscape. Several factors are specifically considered: soil texture, hydraulic conductivity, salinity, geological uniformity, depth to water table and topography. The risk of altering surface and subsurface soil drainage regimes, soil salinity, potential for runoff, erosion and flooding is determined by specific criteria for each property.

Use of this rating is intended to serve as a warning of potential environmental concern. It may be possible to design and/or give special consideration to soil-water-crop management practices that will mitigate any adverse impact.

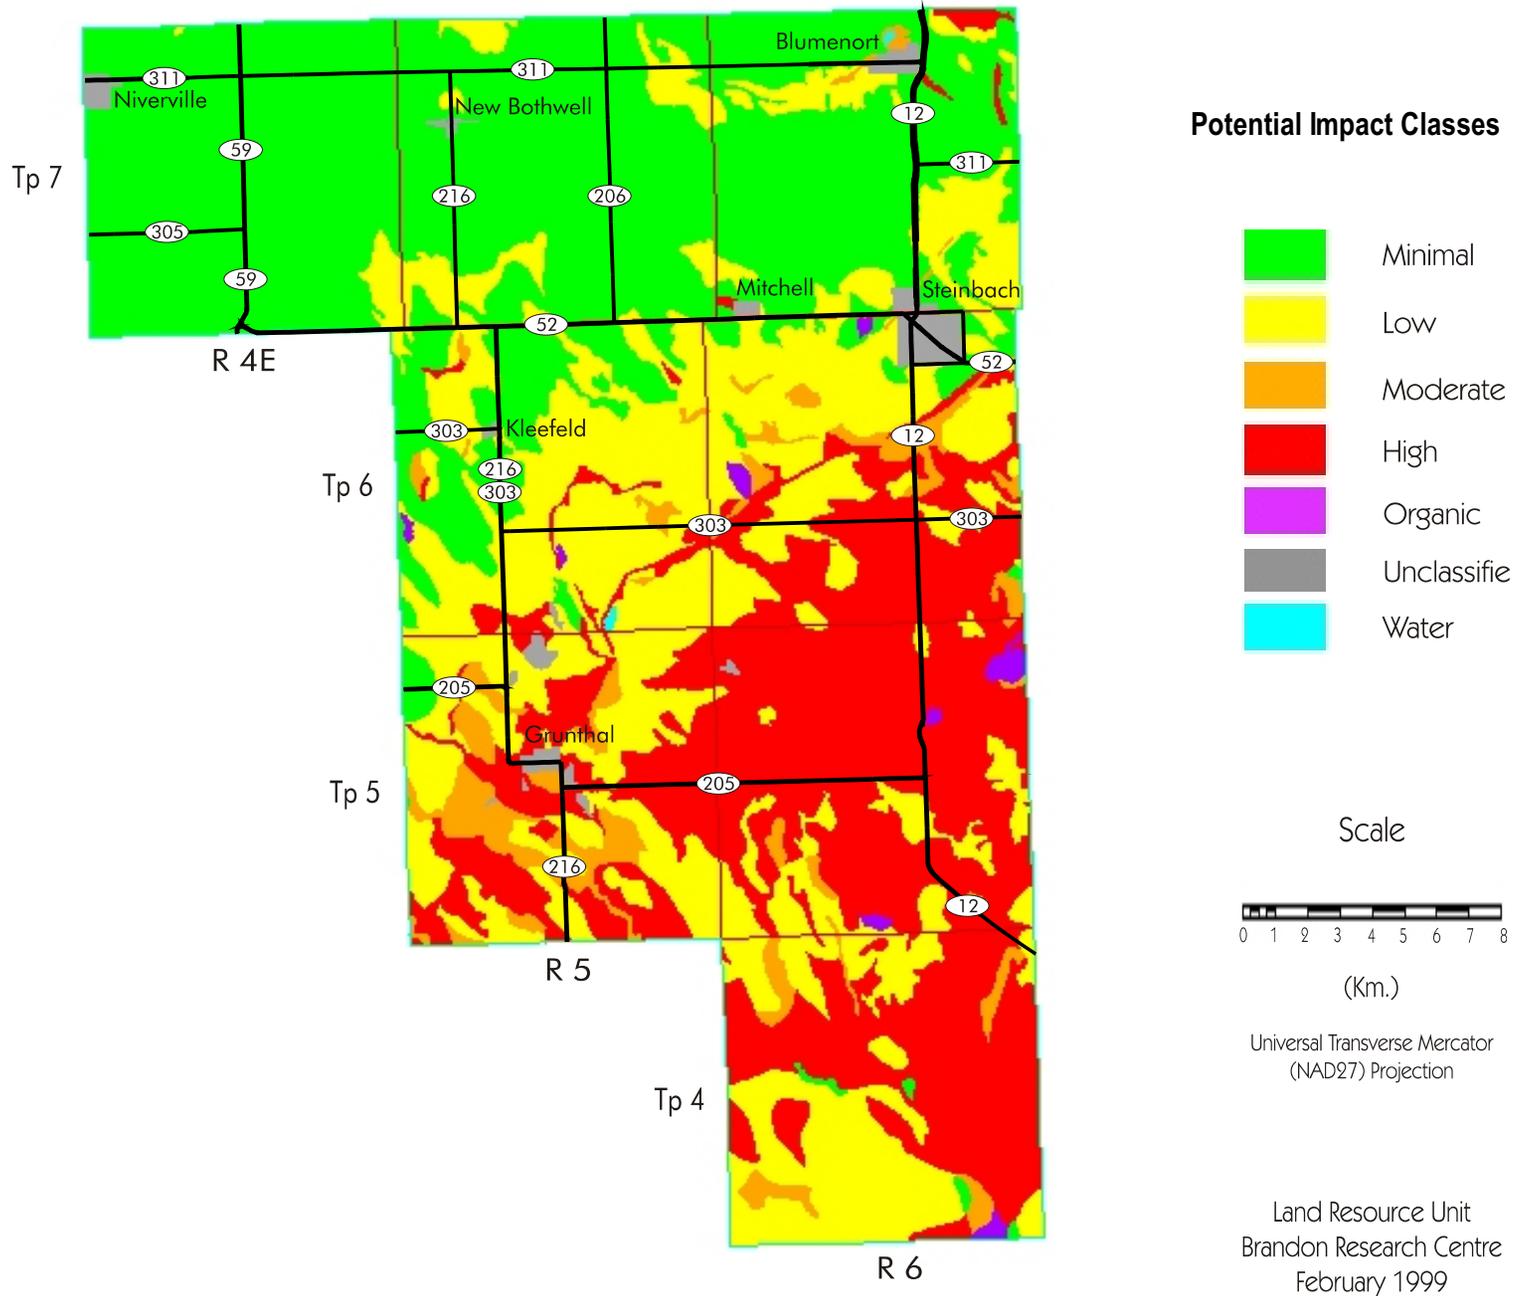

This generalized interpretive map is based on the dominant soil series and slope class for each soil polygon. The nature of the subclass limitations, and the classification of subdominant components is not shown at this generalized map scale.

**Table 7. Potential Environmental Impact Under Irrigation<sup>1</sup>**

<b>Class</b>	<b>Area (ha)</b>	<b>Percent of RM</b>
<b>Minimal</b>	<b>28383</b>	<b>36.8</b>
<b>Low</b>	<b>23564</b>	<b>30.5</b>

<b>Total</b>	<b>77143</b>	<b>100.0</b>

<sup>1</sup> Based on the **dominant** soil series and slope gradient within each polygon.

# Potential Environmental Impact Under Irrigation

**Water Erosion Risk Map.**

The risk of water erosion was estimated using the universal soil loss equation (USLE) developed by Wischmeier and Smith (1965). The USLE predicted soil loss (tons/hectare/year) is calculated for each soil component in each soil map polygon. Erosion risk classes are assigned based on the weighted average soil loss for each map polygon. Water erosion risk factors include mean annual rainfall, slope length, slope gradient, vegetation cover, management practices, and soil erodibility. The map shows 5 classes of soil erosion risk based on bare unprotected soil:

- negligible
- low
- moderate
- high
- severe

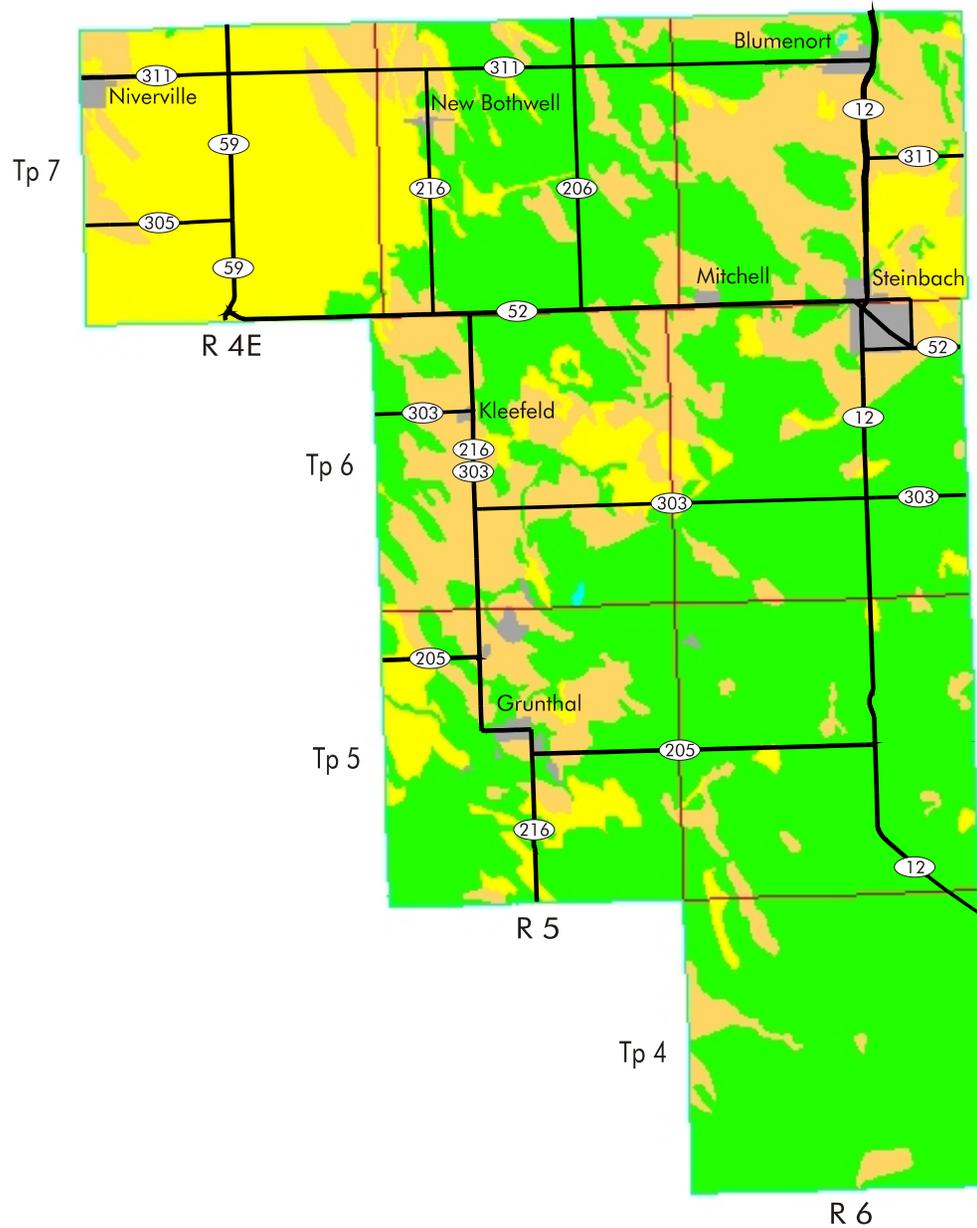

Cropping and residue management practices will significantly reduce this risk depending on crop rotation program, soil type, and landscape features.

**Table 8. Water Erosion Risk<sup>1</sup>**

Class	Area (ha)	Percent of RM
Negligible	44698	57.9
Low	16929	21.9
Moderate	14457	18.7
High	0	0.0
Severe	0	0.0
Unclassified	1042	1.4
Water	17	0.0
<b>Total</b>	<b>77143</b>	<b>100.0</b>

<sup>1</sup> Based on the weighted average USLE predicted soil loss within each polygon, assuming a bare unprotected soil.

**Land Use Map.**

The land use classification of the RM has been interpreted from LANDSAT satellite imagery, using supervised computer classification techniques. Many individual spectral signatures were classified and grouped into the seven general land use classes shown here. Although land use changes over time, and some land use practices on individual parcels may occasionally result in similar spectral signatures, this map provides a general representation of the current land use in the RM.

The following is a brief description of the land use classes:

**Annual Crop Land** - land that is normally cultivated on an annual basis.

**Forage** - perennial forages, generally alfalfa or clover with blends of tame grasses.

**Grasslands** - areas of native or tame grasses, may contain scattered stands of shrubs.

**Trees** - lands that are primarily in tree cover.

**Wetlands** - areas that are wet, often with sedges, cattails, and rushes.

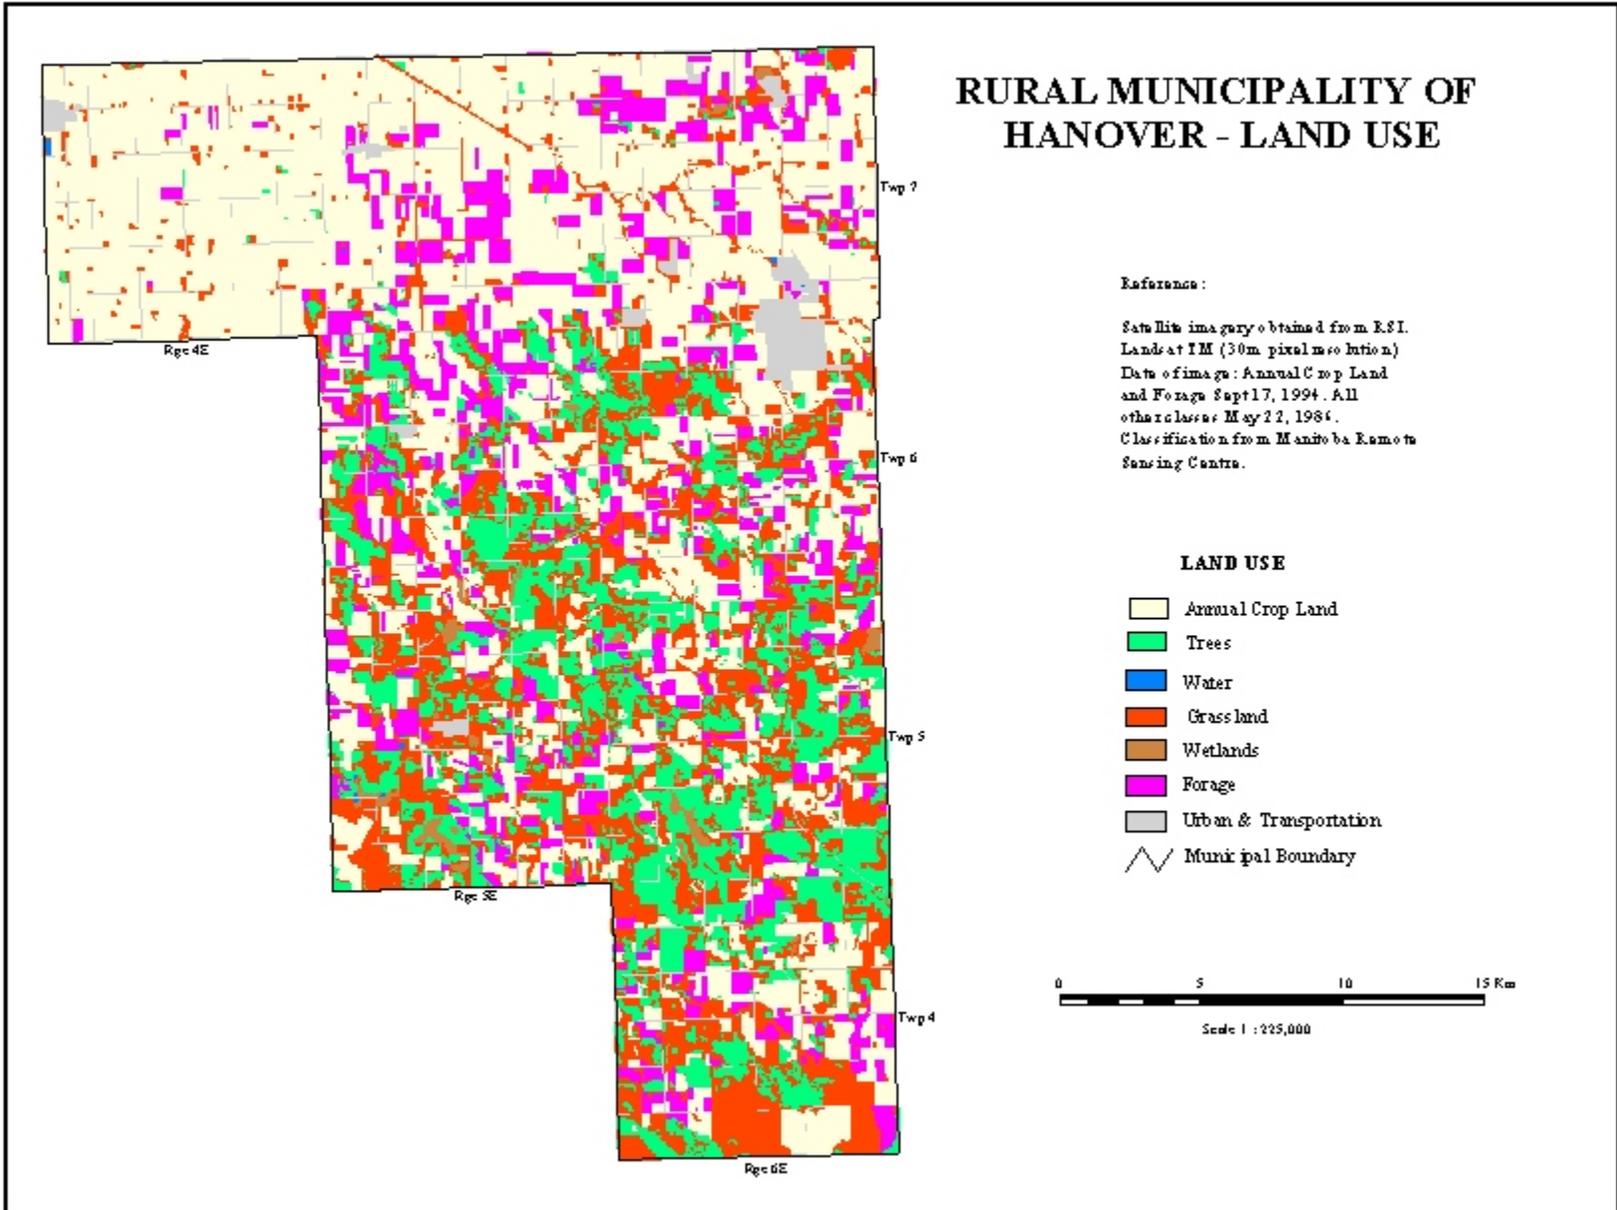

**Water** - open water - lakes, rivers streams, ponds, and lagoons.

**Urban and Transportation** - towns, roads, railways, quarries.

**Table 9. Land Use<sup>1</sup>**

<b>Class</b>	<b>Area (ha)</b>	<b>Percent of RM</b>
<b>Annual Crop Land</b>	<b>34767</b>	<b>44.7</b>
<b>Forage</b>	<b>9113</b>	<b>11.7</b>
<b>Grasslands</b>	<b>17342</b>	<b>22.3</b>
<b>Trees</b>	<b>12089</b>	<b>15.5</b>
<b>Wetlands</b>	<b>526</b>	<b>0.7</b>
<b>Water</b>	<b>36</b>	<b>0.0</b>
<b>Urban and transportation</b>	<b>3954</b>	<b>5.1</b>
<b>Total</b>	<b>77827</b>	<b>100.0</b>
